Forces of Flight Grade 5 Academic Lesson #2

Topics: forces, motion (science)

Length of Lesson: 45 minutes

Objectives:

- Students will identify and define the four forces of flight: weight (or gravity), lift, thrust, and drag.
- Students will demonstrate the four forces of flight.
- Students will experiment with flight.

Next Generation Science Standards:

- Support an argument that the gravitational force exerted by Earth on objects is directed down. (5-PS2-1)
- Plan and carry out fair tests in which variables are controlled and failure points are considered to identify aspects of a model or prototype that can be improved. (3-5-ETS1-3)

CCSS ELA:

- SL 5.4 - Report on a topic or text or present an opinion, sequencing ideas logically and using appropriate facts and relevant, descriptive details to support main ideas or themes; speak clearly at an understandable pace.
- L 5.6 - Acquire and use accurately grade-appropriate general academic and domain-specific words and phrases, including those that signal contrast, addition, and other logical relationships

Background Information:

For a very simple, but clear, description of the four forces of flight, you may wish to watch (and/or share with the students) the video, ["How Do Airplanes Fly?"](#)

Explaining how and why an airplane flies is very complex; however, the following simple explanations will help students acquire an elementary understanding of the [forces of flight](#).

- Thrust is a force that moves an object in the direction of motion. It can be created with a propeller, jet engine, or rocket. With a propeller or jet engine, air is pulled in and then pushed out in an opposite direction. A household fan can demonstrate this. Throwing an object, such as a Frisbee or a paper airplane, also creates thrust. Thrust is the opposite force to drag.
- Drag is the force that acts opposite to the direction of motion. It tends to slow an object. Drag is caused by friction and differences in air pressure. An example of drag is putting your hand out of a moving car window and feeling it pull back. Drag is the opposite force to thrust.

- Weight is the force caused by gravity; the downward force toward the center of the earth. Weight is the opposite force to lift.
- Lift is the force that acts at a right angle to the direction of motion through the air. Lift is created by differences in air pressure. The wings create most of the lift used by airplanes. Lift is created due to angle of attack (the angle that the wings make against the air flowing towards them). Angle of attack relates to Newton's laws of motion. Depending on how the air is "hitting" and moving away from the wing affects the altitude of the plane.

The angle of attack is the angle at which relative wind meets an airfoil (shape of a wing). It is the angle that is formed by the chord of the airfoil and the direction of the relative wind or between the [chord line](#) and the flight path. The angle of attack changes during a flight as the pilot changes the direction of the aircraft. It is one of the factors that determine the aircraft's rate of speed through the air. See [video on Angle of Attack](#) for a demo.

The angle of attack is the angle between the chord of the airfoil and the relative wind.

Notice the clouds in the picture to the right. The positive angle of attack of the wing pushed air down into the clouds behind the airplane thus pushing the airplane up. The airplane did not create the trail by flying through the clouds. The trail was created by the deflected relative wind bouncing off the bottom of the wing.

The increase in angle of attack increases lift up to a point. The angle of attack forces the relative wind hitting the airfoil down. (The relative wind is the flow of air past an airfoil relative to the path of flight. It is parallel and opposite in direction to the aircraft's path of flight.)

By Newton's third law of motion (equal and opposite reaction), the wing is pushed up (lift). Lift is not created without a trade off. The relative wind also pushes the wing backward (induced drag).

At some point, the force of drag is greater than lift as the angle of attack increases. The aircraft will stall (stop flying and start falling), without enough lift. See [What Makes an Airplane Stalls video](#).

Depending on the angle of attack, there will be a force backward (induced drag), and a force upward (lift). The amount of force depends on the angle of attack. If the angle of attack is small, the drag and lift are comparatively small.

Bernoulli's principle helps explain the efficiency of a wing design. Bernoulli's principle explains that there is a difference in air pressure above and below the wing. Faster air moving over the top of the wing creates low pressure, which creates a "pulling" type of effect. Slower air moving underneath the wing creates a higher pressure which provides a "push" upward on the wing. See short demo video [HERE](#) using an airplane's wing. And, a quick demonstration with bathroom tissue and a leaf blower [HERE](#).

Materials:

- "airfoil" pictures which can be used as a transparency showing the cross section of an airplane wing with air traveling over and under it (included)
- "Four Forces of Flight: Illustrations" pictures which can be used as a transparency (included)
- computer with Internet and projector (for use with videos)
- overhead projector (or alternate method of displaying transparency information)
- balsa power plane kits (provided by CAP for the students)
- Frisbee (optional, but good for demonstration)

Lesson Presentation:

1. Pre-assemble a balsa power plane to show the students. [Read the black titled section on Assembly of Guillow's Sky Streak plane, as there are tricks you need to know](#) (such as wing position, fin issues, and lubrication of the motor- which is the rubber band).
2. Tell the students they will be building their own plane today and will be experimenting with its flight. So, ask students if they can explain how an airplane flies. Tell them that they will be able to explain the forces that act upon things that fly as they go through this lesson.
3. Show the "Forces of Flight: Illustrations" transparency/information (included), and briefly describe each force's effect on an airplane. (See background information for explanation of the forces of flight.) Explain lift and gravity last.
 - You can also show the [forces of flight video](#) with simple demonstrations.
 - To help explain the forces of flight, make comparisons to traveling in a car. For example, a car's engine provides the "thrust" needed to move it forward. An airplane's engine and propellers create its thrust.

Lift, drag, and angle of attack are easily observed by sticking your arm out of the car window while riding with hand extended and fingers together. Imagine your arm is now a wing. Rotate your hand to change the angle of attack. At each angle, notice the relative wind hitting your hand. When your hand is parallel to the relative wind (angle of attack = zero degrees) the

relative wind puts pressure on the leading edge of your wing only. Keeping your hand in one place is fairly easy. This is the point where lift and drag are both lowest. Rotate your hand so your thumb is higher than your pinky finger (angle of attack is greater than zero), and your wing finds lift. Notice the relative wind also pushes your hand back (induced drag). Continue rotating your hand and you will find an angle of attack where the drag pulling your arm backwards is greater than the lift. Your wing has stalled.

Now rotate your hand the other direction so that your thumb is lower than your pinky finger. Notice the same rules apply. The angle of attack is negative and the relative wind now hits the top of your hand. The lift is pushing your hand into the ground! A pilot can change the aircraft's angle of attack to fly both up and down through the air. To remain in the air, the aircraft will need lift to continually overcome gravity; therefore, the angle of attack for normal flight is greater than zero. Aircraft wings are designed and built with a positive angle of attack for this very purpose.

3. Show the airfoil transparency with diagram of the air flow over the airfoil. Explain that the curved edge of a Frisbee serves the same purpose as the curved front of the wing. This particular shape is called an airfoil, and it helps create lift. Further explanation should be given: Airplanes are able to fly because of the movement of airflow above and below their wings. As the engine and propellers work together to provide thrust and move the plane through the air, air flows above and below the wing. The angle of attack affects the altitude of the plane, or the plane's lift. Another factor that aids in lift is Bernoulli's principle, which relates to the pressure difference that occurs between the area over and under the wing. Air molecules traveling over the top of the airplane move faster than those moving below the wing. This fast movement of air causes a low pressure above the wing, which creates a "pulling" effect. The slower moving air under the wing creates a higher pressure that creates a "pushing up" effect. Both the pull and push forces work together to keep the plane lifted into the air.
4. Ask students what keeps a car on the ground. (gravity) Ask students to explain why gravity keeps a car on the ground, but not an airplane. If students say a car cannot go fast enough to take flight, dispel that thought by telling them that a small, lightweight aircraft can take off at speeds around 60 miles per hour, and a car can certainly go faster than 60 mph! A German plane was developed in WWII that could take off at about 25 miles per hour! Speed is not the reason a car doesn't lift off of the ground. It has to do with design, specifically wings that generate lift! Airplane wings generate most of the lift for airplanes.

Cars were not designed to fly. Yes, the forces of drag and lift act on a car, but due to the design of cars and the "angle of attack" of their parts against air, they do not take off. In fact, to try to keep race cars, like [Formula One cars](#), from coming off the ground, an inverted airplane wing is located in the front and back of the car. This improves "downforce," which adds more weight on the tires. (Even some regular automobiles utilize a type of inverted wing to correctly and efficiently direct air flow.) This doesn't mean, though, that race cars will never come off of the ground. The right speed and angle of attack (remember, racetracks are not always flat) could

it to lift off of the ground, but it won't stay in the air for long (no continued thrust and wrong angle of attack)! ([See short video of flying Formula One car that crashes, but driver is unhurt.](#))

*** See [Formula One aerodynamics video](#) that compares the angle of attack of the wings of the car with the angle of attack of the wings of an airplane! Cool!

5. Using the bottom picture on the "Forces of Flight" transparency, point to the different arrows and ask the class to name the force indicated by the arrow.
6. Provide a plane kit to each student. Guide students through the building process according to the directions provided in the kit. Or, show a quick video on how to put together the balsa power plane [HERE](#). Watch, also, how to wind the rubber band in a clockwise direction. ***Remind the students to be careful as the balsa wood will break easily! Once the planes are made, have students write their name on their plane, and decorate, if so desired.
7. Have students hold their assembled plane with the propellers pointed toward the front of the classroom. Call out each of the four forces of flight and ask students to orient their planes correctly to show the effect of the force. For example, when you say "thrust," students should move their plane forward. When you say "drag," students should move their plane back. Remind students that each force is necessary in order for airplanes to fly.
8. Ask the students if they know what the motor is that turns the propeller to provide thrust. It is the rubber band! When the rubber band is twisted tightly "elastic potential energy" will be created. When the rubber band is released, "kinetic energy" will be created which will turn the propeller and provide thrust. Demonstrate the clockwise winding of the rubber band and releasing to demonstrate how the 'motor' will turn the propeller and provide the thrust for flight. (Only wind a few times for an inside demo.) Show a [very short demo launch video](#), illustrating how to hold the propeller and let it go while thrusting the plane forward in a smooth and level position.
9. Take the students outside with their planes to demonstrate the forces of flight and experiment with flight. * Go over safety issues with students before flying. - Use safety goggles, if available. Remind the students not to fly airplanes in close proximity to other students and be vigilant at all times.) You may wish to take some tape outside to help with any necessary flight repairs.
10. While the students practice flying their plane, have them discuss amongst each other which forces are and are not working well. If the plane is shooting straight up and then back down, they probably are using the wrong angle of attack in their throwing of the plane to start. Help them determine what adjustments they need to make to their airplanes to make them fly longer and farther- trying to balance these four forces. Continue flying until time to go back inside.

Summarization:

Ask students to share their flight experiences. Ask them to identify problems they encountered with their flights and any solutions at which they arrived. Ask students the following review questions.

- What provided thrust for their airplane? (the rubber band and propellers)
- What eventually brought the airplane back to the ground? (gravity)

- What force worked against the forward motion of the airplane? (drag)
- What force helped hold the airplane in the air while thrust was being generated? (lift)
- Ask students if they have any ideas as to why lift occurred with the airplanes even though the wing is not curved like an airfoil? (orientation of the wings to the air - angle of attack)

Character Connection: Tell students that just like there are forces that affect flight, there are forces all around us that affect our lives. Some of the forces are good and some bad. For example, the force of peer pressure might cause us to do something we will regret if peers are pressuring us to do something wrong. Our parents, teachers, coaches, and other adults in our lives can be a strong force in our lives to encourage us to do good things. Media (television, movies, magazines, etc.), can be a force that influences our decisions. Encourage students to be aware of the forces around them and make good decisions that will positively impact their lives. Encourage them to be a positive force to motivate others to make good decisions, as well.

Drug Demand Reduction (DDR) Connection: See page 10.

Assessment:

- teacher observation
- construction and flight of airplane
- "Four Forces of Flight" worksheet (optional)

Additional activity ideas to enrich and extend the primary lesson (optional):

- Have students complete the "Four Forces of Flight" worksheet.
- Present the following information about Frisbees:
Many people claim to have invented the Frisbee. They got their start in New England colleges during the 1800s when students would fling empty pie tins from the Frisbee Baking Company for fun. In 1948, a Los Angeles man named Walter Frederick Morrison invented the first plastic version that flew further and with better accuracy than the pie tin.
Just like the shape of an airplane, the shape of a Frisbee has a great deal to do with its ability to soar through the air. A Frisbee is an airfoil, just like the wing of an airplane is an airfoil. An airfoil-shaped body moving through the air produces a force called lift. A Frisbee's spinning action creates stability for the Frisbee, the same way that airplanes and birds have tails, and rockets have fins to help keep them stable during flight.
Activity: Have students demonstrate the four forces of flight with a Frisbee. Have them experiment with Frisbees of different shapes and sizes and draw reasonable conclusions.
- Divide students into small groups. Have groups determine other ways that they can demonstrate the four forces of flight. Then, let the groups share their ideas with the class.
- A really good 9.5-minute video is found [HERE](#) that goes from the construction of a plane's parts to make the plane, to how the parts work to make the airplane fly, to an actual flight, maneuvers in the air, and a landing. Worth the students' viewing, if there is time.

- Have students compare and contrast the four forces of flight on an airplane in a Venn diagram. Remind students that each force has an opposite force that works against it.

FORCES OF FLIGHT

Name _____

Write the name of the force of flight represented by each arrow.

Write the letter of the correct term beside each description. You may use a letter more than once!

A. Lift B. Drag C. Thrust D. Weight (or Gravity)

- _____ 1. The special shape of the wings and how air moves over the wings creates this force.
- _____ 2. This is a force that moves the object in the direction of motion. An engine or a propeller can create this force.
- _____ 3. This force is the air resistance affecting a moving object. It seeks to slow down the object.
- _____ 4. This force always pulls downward.
- _____ 5. This force is opposite of drag.
- _____ 6. A demonstration of this force is putting your hand out of the window of a moving car and feeling the air pushing your hand back.
- _____ 7. This force is the opposite of gravity or weight.

Forces of Flight Answer Sheet

Write the name of the force of flight represented by each arrow.

Write the letter of the correct term beside each description. You may use a letter more than once!

A. Lift B. Drag C. Thrust D. Weight (or Gravity)

- A 1. This force is created by the special shape of the wings and how air moves over the wings.
- C 2. This is a force that moves the object in the direction of motion. An engine or a propeller can create force.
- B 3. This force is the air resistance affecting a moving object. It seeks to slow the object.
- D 4. This force always pulls downward.
- C 5. This force is opposite of drag.
- B 6. A demonstration of this force is putting your hand out of the window of a moving car and feeling the air pushing your hand back.
- A 7. This force is the opposite of gravity (or weight).

Civil Air Patrol's ACE Program

Graphing the Four Forces Grade 5 Academic Lesson #3

NOTE: this lesson should follow Academic Lesson #2

Topics: forces, graphing (science, math)

Lesson Reference: [Re-Living the Wright Way](#)

Length of Lesson: 45 minutes

Objectives:

- Students will describe the four forces of flight (lift, weight/gravity, thrust, drag).
- Students will determine the net force of two objects.
- Students will graph information to determine whether or not a plane is flyable.
- Students will make inferences using the graph results.

CCSS ELA:

- SL 5.4 - Report on a topic or text or present an opinion, sequencing ideas logically and using appropriate facts and relevant, descriptive details to support main ideas or themes; speak clearly at an understandable pace.
- L 5.6 - Acquire and use accurately grade-appropriate general academic and domain-specific words and phrases, including those that signal contrast, addition, and other logical relationships

CCSS Math:

- 5.G.A.1 Use a pair of perpendicular number lines, called axes, to define a coordinate system, with the intersection of the lines (the origin) arranged to coincide with the 0 on each line and a given point in the plane located by using an ordered pair of numbers, called its coordinates.

Background Information: (From NASA Quest, now archived)

A force is defined in its simplest sense as a "push" or a "pull." These definitions do not imply a direction. Students can "pull" in any direction just as they can "push" in any direction. The terms are frequently used because students can readily identify with the actions of pushing and pulling, and the fact that these actions usually have an effect on what they are pushing or pulling.

Review with students that there are two parts to the definition of a force. In fact, when a force is defined it must have both parts - one is not enough! The two parts are: magnitude (a quantity that can be measured) and direction. The direction of a force is self-explanatory, and again, has nothing to do with the terms "push" or "pull."

The magnitude of a force can be described as "how hard the force is" or "how much power the force has." For example, a force of magnitude 10 can be described as a "stronger" force than one of magnitude 2, which can be described as a "weaker" force.

When two forces act in parallel, in either the same or opposite direction, measuring them is simply a matter of adding or subtracting their magnitudes. When two forces are acting in parallel and in the same direction, measure them by adding the magnitudes together. See more information in [NASA: Equilibrium of Forces](#). There is also a very good video, [What is Force, Part 1](#).

In the example to the right, a "push" of magnitude 1 added to a "pull" of magnitude 1 equals a net force of magnitude 2. The cart will then move in the direction of the net force - in this case to the right.

Push 1 + Pull 1 = Net Force 2 to the right

When two forces act in parallel in the opposite direction, we get the net force by subtracting the magnitudes. In the example to the right, a pull of magnitude 1 is acting opposite to a pull of magnitude 2. The cart will move in the direction of the net force. In this case, the cart will move to the left, at magnitude 1.

Pull 2 - Pull 1 = Net Force 1 to the left

Forces that act in opposite directions are called "oppositional" forces. Four of the forces in aeronautics (lift, drag, weight, and thrust) can be thought of as "oppositional" pairs.

thrust acts in a direction opposite to drag
lift acts in a direction opposite to weight

The oppositional forces can be introduced as a game of tug-of-war. Teams can be named as the four forces. For example, a tug-of-war can be set up between a thrust team and a drag team.

In the above graphic, the "Thrust Team" has a magnitude of 4 and the "Drag Team" has a magnitude of 3.

The net force will be Thrust 4 - Drag 3 = Net Force 1 to the right.

Since the "Thrust Team" has the greater magnitude, the cart will move in the direction that the "Thrust Team" is pulling, in this case to the right.

Materials:

- overhead projector and transparencies of the introduction pictures or alternate means of showing the images
- copies of "Graphing the Four Forces" worksheets

NOTE: This lesson is more effective if students have received a forces of flight lesson, such as the ACE Grade 5 Academic Lesson #2 entitled, "Forces of Flight."

Lesson Presentation:

1. Review information about the four forces of flight by asking students to share information about the forces of flight. Allow them to illustrate the information on the board if they prefer.
2. Explain to students that they will use information about the four forces of flight today to make a decision about whether or not a plane is able to fly. Explain that this is in theory - as there are other factors regarding the plane that would be taken into consideration.

3. Show students introductory picture #1. Tell students that in the case of this graph, direction is determined by the force of flight. Point out that lift is "up toward the top of the paper," weight (or gravity) is "down toward the bottom of the paper," thrust is "forward toward the right of the paper," and drag is "back toward the left of the paper." Lift and weight are parallel forces. Thrust and drag are parallel forces.

Tell students that they will use magnitudes (to be defined later), for each force of flight to plot points on the graph. Once all points are plotted correctly, it should be easy to determine if the overall forces of flight affecting the plane will allow it to fly.

4. Distribute student copies of "Graphing the Four Forces." Tell students to follow along on their student sheet for the example as you demonstrate the process to the class. Follow the directions on the page. You may choose to use introductory picture #2 to demonstrate how to correctly graph the magnitudes of each force in order to reveal the net force.

5. Once the example problem is completed, ask students if they have an idea of what "magnitude" means as it is used with each force of flight. Confirm that magnitude, as it is used in the examples, is a number that describes the amount of force. To fully describe a force acting upon an object, not only does one need to know the direction, but also magnitude. For example, if Bob weighs 100 pounds and he stands on a chair, he is applying a downward force of 100 pounds on the chair. The reverse is also true; the chair is applying an upward force of 100 pounds. With our forces of flight, we know how the force affects direction. Lift is up, weight/gravity is down, thrust is in the front of the plane, and drag is at the rear. As NASA Quest explained, "The magnitude of a force can be described as 'how hard the force is' or 'how much power the force has.' For example, a force of magnitude 10 can be described as a 'stronger' force than one of magnitude 2, which can be described as a 'weaker' force."

force." In the forces of flight graphing activity, the given magnitudes of the forces of flight help one to better understand the "power" of each force and to plot the forces on the graph.

6. Ask students if they can define "net force." If help is needed, display "introductory picture #3," and explain the pictures to the students. The examples in "introductory picture #3" simplify the concept of net force by adding or subtracting only two parallel forces. Explain that in the graphing exercise they just completed, they did not take into account only two parallel forces, they "added" all four forces of flight which resulted in the net (overall total) force acting on the object, which, in this case, is an airplane.
7. Ask students if they have any questions about how to plot the forces of flight using direction and magnitude. If there are no other questions, allow students to complete the other problems provided.
8. Either collect the papers to grade or go over the answers with the students.

Summarization:

Ask students to share what they learned today. Ask students to share their definition of the following: lift, thrust, weight, drag. Ask students what two components are necessary to fully describe a force acting upon an object. (direction and magnitude) Ask students to explain what magnitude means, as it relates to forces. (magnitude, as it is used in the examples, is a number that describes the amount of force) Ask students to explain net force. (the overall total force acting on an object)

Ask students why it is important to know how to use a graph. (Plotting information on a graph creates a visual representation of information which can make information easier to understand. Information on a graph can reveal important information.)

Character Connection:

Tell students that in life, forces push and pull us. Sometimes, forces want to pull or push us in the wrong direction. Just like the forces of flight graphs reveal whether or not a plane will fly, we should consider making a visual representation of how positive forces can "lift" us up and negative forces can bring us "down," or cause us to go backward instead of moving forward. When faced with making a choice, decide if your answer will place you on the side of "lift" and "thrust" or will it place you in a position of "drag" and "weight."

Assessment:

- teacher observation
- student answers to class discussion questions
- "Graphing Forces of Flight" worksheet

Additional activity ideas to enrich and extend the primary lesson (optional):

- Make copies of "introductory picture 2," and allow students to create their own magnitudes for each force of flight and plot it on a graph. Allow students to exchange sample problems to see if a classmate confirms the same results.
- Discuss with students the answers to the "expert questions" on the "Graphing the Four Forces" problems for numbers 1-4. Explain to the students that the graph information tells us so much more than just whether or not the plane will fly. If we fully understand the forces of flight and the graph information, we can easily discern how to make the airplane flyable if it was identified as "not flyable" after calculating the net force.
- Teach or have students write the plotted points of lift, weight, drag, thrust, and net force for each problem with actual x and y coordinates, such as (-2, 7).
- Discuss further how to calculate the net force of two opposing forces, as discussed in the background information. Then, allow students to complete the "Use the Force" worksheet.

Associated Websites:

Introductory picture #1 (Graph)

Introductory picture #3 (Net Force)

When two forces act in parallel, in either the same or opposite direction, measuring them is simply a matter of adding or subtracting their magnitudes.

When two forces are acting in parallel and in the same direction, measure them by adding the magnitudes together. In the example below, a "push" of magnitude 1 added to a "pull" of magnitude 1 equals a net force of magnitude 2. The cart will then move in the direction of the greatest magnitude - in this case to the right.

When two forces act in parallel in the opposite direction, measure them by subtracting the magnitudes. In the example below, a pull of magnitude 1 is acting opposite to a pull of magnitude 2. The cart will move in whichever direction has the greatest magnitude. In this case the cart will move to the left.

Forces that act in opposite directions are called "oppositional" forces. Four of the forces in aeronautics (lift, drag, weight, and thrust) can be thought of as "oppositional" pairs.

thrust acts in a direction opposite to drag

lift acts in a direction opposite to weight

In the above graphic, the "Thrust Team" has a magnitude of 4 and the "Drag Team" has a magnitude of 3.

The net force will be: Thrust 4 - Drag 3 = Net Force 1 to the right. Since the "Thrust Team" has the greater magnitude, the cart will move in the direction that the "Thrust Team" is pulling, in this case to the right.

GRAPHING THE FOUR FORCES

NAME _____

Example

Directions: Follow along as your teacher demonstrates how to plot the magnitudes listed for the forces of flight in order to determine the net force. The net force will reveal whether or not the airplane can fly.

Using the magnitudes for each force below, follow the steps and plot your points on the graph.

Weight	3 units
Lift	7 units
Drag	2 units
Thrust	5 units

Step 1:	Start at the origin and count down three squares (for weight). Plot a small dot.
Step 2:	From that small dot (do not start again from the origin!) count up seven squares (for lift). Plot another small dot.
Step 3:	From that small dot (do not start again from the origin!) count to the left two squares (for drag). Plot another dot.
Step 4:	From that small dot (do not start again from the origin!) count to the right 5 squares (for thrust). Plot a large dot. This is the representation of the net force.
Step 5:	<p>Determine whether or not the airplane is flyable.</p> <p>If the net force is plotted in the upper right quadrant, the airplane is flyable.</p> <p>If the net force is plotted in the upper left quadrant, the airplane is not flyable; it has too much drag.</p> <p>If the net force is plotted in the lower left quadrant, the airplane is not flyable; it has too much drag and weight.</p> <p>If the net force is plotted in the lower right quadrant, the airplane is not flyable; it has too much weight.</p>

GRAPHING THE FOUR FORCES

NAME _____

Directions: Use the magnitudes provided for each force to determine whether or not the plane can fly. If the plane cannot fly, explain why.

Problem #1.

Weight	4 units
Lift	10 units
Drag	2 units
Thrust	10 units

#1 _____

Will the plane in problem #1 fly? _____

If the plane does not fly, why doesn't it fly?

Expert level: If the plane does not fly, what could be done to make it fly?

Problem #2.

Weight	8 units
Lift	4 units
Drag	6 units
Thrust	4 units

#2 _____

Will the plane in problem #2 fly? _____

If the plane does not fly, why doesn't it fly?

Expert level: If the plane does not fly, what could be done to make it fly?

Lift	10 units
Drag	2 units
Thrust	2 units

Explain what is happening with the "bonus" plane. What could it be?

USE THE FORCE

Name _____

1:	Define the word "force".
2:	<p>Complete the sentences below by filling in the blanks.</p> <p>A force can move in different_____.</p> <p>A force has strength or _____that can be_____.</p> <p>Parallel forces can be added or_____.</p>
3:	<p>An F-14 is flying west. Its engines are creating a thrust force of magnitude 4,000. A strong headwind is blowing to the east creating a drag force on the F-14 of magnitude 1,000.</p> <p>What is the net force on the F-14? _____</p> <p>In what direction will the F-14 fly? _____</p> <p>Draw a picture of this event. Make sure you include the F-14, the wind, arrows to represent the magnitudes, and the equation that gives the net force. Draw one arrow for each 1,000 units of magnitude.</p>
4:	<p>After the Space Shuttle is launched, its huge rocket engines lift it upward with incredible force. As it blasts through the top of the atmosphere into outer space, the engines are creating a force pushing <u>up</u> into space with a magnitude of six times the force of gravity. We write this as "6g".</p> <p>The gravity force is pulling the Shuttle <u>back</u> down in the direction of the earth with a magnitude of one times the force of gravity. We write this as "1g".</p> <p>What is the net force on the Space Shuttle? _____</p> <p>Draw a picture of this event to help you answer the question. Be sure to include the Shuttle, the Earth, arrows to represent which direction the engines and the earth are pulling, and the equation that gives the net force. Draw one arrow for each g.</p>
5:	<p>Four people are pulling on ropes attached to a cart. Each person is pulling with a magnitude of 1. Two people are pulling to the right and two are pulling to the left.</p> <p>What is the magnitude of the net force? _____</p> <p>In which direction will the cart move? _____</p> <p>Draw a picture of this event to help you answer the questions. Be sure to include the cart, the people, arrows to represent the directions that the people are pulling, and the equation that gives the net force. Draw one arrow for each unit of magnitude.</p>

"GRAPHING THE FOUR FORCES" ANSWER KEY

Note: the arrows may be drawn in any order; you will always end up at the same place!

Problem 1 - Key

Starting at the origin:

The end of the weight arrow will be at (0,-4). The end of the lift arrow will be at (0,6).

The end of the drag arrow will be at (-2,6.) The end of the thrust arrow will be at (8,6).

*Since (8,6) is in the upper right quadrant (quadrant I), the airplane **IS flyable**.*

Problem 2 - Key

Starting at the origin:

The end of the weight arrow will be at (0,-8). The end of the lift arrow will be at (0,-4).

The end of the drag arrow will be at (-6,-4). The end of the thrust arrow will be at (-2,-4)

*Since (-2,-4) is in the lower left quadrant (quadrant III), the airplane is **NOT flyable**.*

Both weight and drag are too great. Possible answers to make the plane flyable: To make the plane fly, the plane needs weight to decrease or lift to increase. This could occur if the plane were lighter or if the plane's wing design was improved. Drag needs to be decreased or thrust needs to increase. This could occur if the design of the plane changed to reduce drag or if the engines provided more thrust.

Problem 3 - Key

Starting at the origin:

The end of the weight arrow will be at (0,-3). The end of the lift arrow will be at (0,3).

The end of the drag arrow will be at (-8,3). The end of the thrust arrow will be at (-3,3)

*Since (-3,3) is in the upper left quadrant (quadrant II), the airplane is **NOT flyable**.*

Drag is too great. Possible answers to make the plane flyable: To make the plane fly, the plane needs drag decreased or thrust increased. This could occur if the design of the plane changed to reduce drag or if the engines provided more thrust.

Problem 4 - Key

Starting at the origin:

The end of the weight arrow will be at (0,-4). The end of the lift arrow will be at (0,5).

The end of the drag arrow will be at (-2,5.) The end of the thrust arrow will be at (5,5).

*Since (5,5) is in the upper right quadrant (quadrant I), the airplane **IS flyable**.*

Bonus

*The end result is (0,8). The plane **could be flyable, provided the plane is designed to be able to adjust its thrust**. Since the thrust equals the drag in this problem, the plane is not moving forward or backward. This could be a helicopter or a flying saucer hovering over a specific place!*

"USE THE FORCE" ANSWER KEY

1: A force is a "push" or a "pull". It has two parts: magnitude and direction.

2: Directions
magnitude, measured
subtracted

3: 3,000
West
thrust 4,000 - drag 1,000 = net force 3,000 in the direction of thrust

4: 5g
up 6g - down 1g = net force 5g in up direction **or**
lift 6g - weight 1g = net force 5g in direction of lift

5: 0
neither
pull 1 - pull 1 = net force 0

GRAPHING THE FOUR FORCES

NAME _____
